have the properties of a metallic bonding but at the same time it is distinguished by the property of saturability: along with the bonding orbits, if the number of electrons in the compound exceeds a certain level, there appear orbits which weaken the bonding. The presence of bonding orbits conditions a definite proportion of covalence and the attendant properties: hardness, chemical inertia, etc. The strength of bonding, given an equal number of electrons, is determined by the electrostatic interaction between d-, s-, and p-electrons and the nuclei of the metal and metalloid, on taking into account the shielding effect of the internal electrons; the weaker this electrostatic attraction is, the stronger is the bonding in the compound. The strongest bonding in the carbides, nitrides, and borides of the transition metals is observed in cases where there are 5.5-6.5 electrons per metal atom; it is exactly in these cases that the melting points of such compounds are the highest (upward of 2600°C) and they are the most heat-resistant. This is exemplified by the case of titanium carbide: The electronic structure of Ti is 3d24s (beyond the argon shell), and that of C, 1s22s22p2. Total number of bonding electrons: two 3d- and two 4s-electrons from Ti, minus 0.5 electron departing for the conductivity band, plus two 2p-electrons from C. Thus, the sum total of the electrons considered is 5.5. Orig. art. has:

TITLE: Investigating reliability of USEPPA discrete elements

SOURCE: Priborostroyeniye, no. 11, 1966, 25-27

TOPIC TAGS: pneumatic control element, pneumatic control system / USEPPA. pneumatic control system

ABSTRACT: The preliminary results are reported of an investigation of reliability of USEPPA pneumatic-control elements fabricated by the Ust!-Kamenogorsk Instrument Plant. Lack of time and continuous modernisation of

Card 1/2

UDC: 62.525 "401.7"

ACC NR: AP6036719

elements did not permit conducting a thorough investigation. Tests in "yes-no" circuits were conducted at frequencies up to 2.5 cps (some up to 10 cps), at 25C and 40-70% humidity; the elements were regarded as nonrepairable equipment; supply pressure, 1-4 kg/cm; twelve different types of elements were tested. The values of the mean time to failure are tabulated. It was found that:

(1) Relay-type elements have a least reliability in the 2.5-5-cps range; (2) The mean time to failure for diaphragm- and shutter-type elements has the same order of magnitude and is practically independent of their circuits; (3) The use of a supply pressure of 1 kg/cm², instead of 1.4 kg/cm², increases the reliability of the elements tenfold; (4) Generally, the failures were caused by wear, and their distribution seems to obey the normal law. Details of tests and hints for modernization are discussed. Orig. art. has: 4 figures, 4 formulas, and 1 table.

Investigation of Turbulent Pulsations of the Air Flow With Semiconductor-Heat-Resistances (Issledovaniye turbulentnykh pul'satsiy vozdushnogo potoka poluprovodnikovymi termosoprotiv-

leniyami)

PERIODICAL: Izvestiya Akademii nauk Uzbekakoy SSR, Seriya fizikomatematicheskikh nauk, 1959, Nr 2, pp 83-87 (USSR)

ABSTRACT:

The author describes a thermistor used for the investigation of turbulent pulsations of the air flows. The apparatus is heated by electric current and simultaneously it is cooled by the air flow. The use bases on the connection between the heat emission of the apparatus and the velocity of the air flow. The given scheme contains two milliammeter, 2 resistances, 1 bifurcation, 1 voltmeter, 1 electronic voltage stabilizer, 1 switch, and 1 oscillograph. The measurements were carried out in air ducts; the

size of the apparatus is so small that even the turbulence inside of the boundary layer can be measured.

TITLE:

A novelty in the technology of machining the separating faces of turbine frame parts. (Novoye v tekhnologii obrabotki ploskostey raz'emov korpusnykh detaley turbin.)

PERIODICAL: "Energomashinostroenie" (Power machinery construction), 1957, No. 5, p. 31, (U.S.S.R.)

ABSTRACT:

In machining the separating faces of turbine frame parts a good surface finish and a high accuracy are required. the Khabarovsk Engineering Works these requirements were formerly met by hand scraping. Then scraping was replaced by grinding using a special grinding head on a milling machine. At the beginning of 1956 an attempt was made simply to cut these surfaces with a wide tool. This was unsuccessful mainly because the lathe could not give cutting speeds lower than five metres per minute or greater than 70 metres per minute. However, a young machine operator, G.E. Namakonov, has succeeded in machining the surfaces of twenty different kinds of parts on a large boring mill. The productivity is twice as great as with grinding. The finishing cut is made with a depth of 0.1 - 0.2 mm with a feed of 0.25 - 0.4 mm per rev depending on the dimension and shape of the parts. cutting speed varied from 100 - 300 metres per minute. The design of cutting tool and other similar features are discussed The complication and expense of equipping a planing machine for grinding and the difficulty of obtaining suitable grinding

TITLE: Measuring rate-of-flow by the average value of dynamic pressure

SOURCE: Izmeritel'naya tekhnika, no. 11, 1964, 54-55

TOPIC TAGS: flow meter 15

ABSTRACT: A method for measuring gas or air flow in short (2-3 m) straight pipes of any size is described. Applicable to combustion measurements, etc., the method is based on measuring the arithmetic mean value of the dynamic pressure by a special flat twin tube with nozzles. The tube measures both static and dynamic pressures by means of a micromanometer. Formulas for correction factors are supplied. Orig. art. has: 2 figures and 4 formulas.

TITLE:

On the failure of turbine discs when operating at a "reverse" temperature gradient

PERIODICAL:

Referativnyy zhurnal, otdel'nyy vypusk. 42. Silovyye ustanovki, no. 15, 1962, 30, abstract

42.15.184 (In collection Teplovyye napryazheniya v elementakh turbomashin, Kiev, AS

UkrSSR, no. 1, 1961, 150-155)

TEXT: The analysis of turbine disc operation at "reverse" temperature gradients, shows that the stressed state of the turbine disc periphery under such conditions is liable to cause disc failure. Reliable operation of turbine discs in mobile turbine plants requires a more detailed study of the effect of temperature gradients on the carrying capacity of discs under cycling working conditions and stress concentrations.

Were injected into guinea pigs, rabbits and mice. Infection was obtained only in the guinea pigs with an intradermal injection of the culture and according to the method of Pak or Blokh. Four to five passages through the organism of the guinea pigs strengthened the virulence of the cultures -- it caused the death of the animal from sepsis both in intravenous and intraperitoneal injections.

TITLE:

The use of Radio Isotopes when Investigating the Kinetics of Scrap Fusion and Slag Formation in the Scrap-Ore Process. (Prime nenive radioaktivnykh isotopov dlya izucheniya kinetiki plavleniya skrapa i shlakoobrazovaniya pri skrap-rudnom protsesse)

PERIODICAL:

Atomnaya Energiya, 1957, Vol. 3, Nr 10, pp. 352-355 (USSR)

ABSTRACT:

1) Investigation of the kinetics of scrap fusion. The fusion velocity in the 130 and 350 ton open hearth furnaces is shown on the basis of the reduction of the specific activity of standard metal samples (400 g), which contain Co-60 with the help of 12 counting tubes of the MC-4 type. From the dependence obtained between the molten scrap quantity and

the time which as elapsed since introduction of the scrap, it follows that nearly 100% of the scrap is molten already after about

2) Investigation of the kinetics of slag formation. CaO, in which Ca-45 was included, was used for this investigation. The CaO is introduced into the liquid slag in closed metallic tubes and standard samples for measuring are taken out only after a lapse of time of 30-35 minutes. As measurement for the velocity in which Ca dissolves in the slag, the relation

The Use of Radio Isotopes When Investigating the Kinetics of Scrap 89-10-22/36 Fusion and Slag Formation in the Scrap-Ore Process.

 $\frac{dx}{dt} = K_{SCH} (100 - x)^{2/3}$ was experimentally confirmed.

x here denotes the weight of the CaO already dissolved and KSCH the proportionality coefficient for slag formation. There are 4 figures and 2 Slavic references.

"Radar Wethod of Determining Breaks in Communication Lines," 7. K. Kuleshav, Jandidate in Technical Sciences, V. O. Shvartsman, Engr., 22 pp

"Yestnik Svyazi - Elektrosvyaz'" No 1 (82)

Describes the operation of the "reflectometer" which uses a radar principle of determining the point of break in a communication table. It works on the principle that a break will return a certain volume of the impulse sent over the line, and the strength of the impulse will determine the approximate location of the break. Photograph of the apparatus and some diagrams showing oscillograph recordings of the apparatus.
